The problem

Detect fraudulent card and account transactions. For each row of test.csv, predict the probability (0 to 1) that the transaction is fraud, from its amount, hour, merchant category, country, channel, the account's recent activity and age, and whether a new device was used. Fraud is rare (under 2% of training rows) and some feature values are missing. Scored by PR-AUC: higher is better.

Your prediction file must have the columns `id,prediction`, with IDs like `FR000001`.

Get your first score in four steps

1. Download `train.csv`, `test.csv` and `sample_submission.csv` below.
2. Train a model on your own machine.
3. Write predictions in the sample_submission format.
4. Upload it on the Submissions page. You will see your public score and rank within seconds.

Downloads

requirements-image.txt 0.3 KB	sample_submission.csv 128.9 KB
template_notebook.ipynb 2.8 KB	test.csv 706.6 KB
train.csv 1220.0 KB	

What you submit

1. **Prediction CSVs** for `test.csv`, in the format of `sample_submission.csv`. Each is scored on the public leaderboard.
2. **A prediction notebook, your trained model file(s) and an optional** `requirements.txt`, in three upload cards on the Notebook & report page. Train on your own machine using `train.csv` (that notebook is not uploaded); the prediction notebook only loads your model and predicts, with **no training cells**. The platform runs it in a sandbox as soon as you upload, so you learn early that it works. One upload per 2h 00m 00s; a failed run uses up that window.
3. **A 1-page technical report** (PDF), uploaded on the *Notebook & report* page. Follow the report format published by the organizers.

Train with the platform's library versions (`pip install -r requirements-image.txt`), or your saved model may not load there.
